1 Experiment Design

Our research method involved a Randomised-Controlled Trial (RCT) of messaging in an online survey experiment. The advantage of this approach is that it allows us to test a range of innovative messages on a large sample of respondents with swift feedback on their expressed investing preferences. This approach serves as a test-bed for potential interventions which could be implemented in a real-world setting, which requires significant investment in modifying consumer journeys, monitoring consumer outcomes and ensuring compliance. Our approach is therefore a first-step in innovation which can inform real-world trials at a later stage. We conducted two phases of the RCT.

1.1 Phase I

Phase I tested between three risk warnings incorporated into the customer journey screens. The control journey showed a standard risk warning, followed by an allocation task in which subjects were asked to allocate a hypothetical portfolio of £10,000 across a variety of investment options. This journey is shown in Figures 1 and 2. The first treatment showed an alternative risk warning emphasising positive returns to stock and fund investments over longer time periods, shown in Figure 3. The second treatment showed the same warning as the first treatment, with the addition of a graph illustrating the returns, shown in Figure 4.

The standard risk warning resembled that used by most financial services providers offering saving and investing products: “The value of investments can fall as well as rise. There is a chance you might not get back what you put in”. This standard risk warning communicates to consumers the possibility that they might make a loss from an investment, but does not quantify the loss nor contextualise the time period over which losses or gains are more likely to be achieved.

The first treatment added this further sentence: “But over longer periods of time (e.g. 5 years or more), riskier investments such as stocks, shares and funds usually give you higher returns compared to cash savings.” This additional message draws attention to the reliably higher returns offered by stocks, shares and funds when invested over longer periods of time.

It is crucial for our study that this statement is substantiated by evidence. The widespread

evidence base showing that investments such as stocks, shares and funds offer higher returns compared to cash savings goes back at least to the work of Mehra and Prescott (1985) and more recently Fama and French (2002). Crucially for the claim of the first treatment statement, the 2019 Barclays Equity Gilt Study demonstrated using historic data from 1899 onwards shows that there is a 76% probability of returns on UK equities outperforming returns cash savings over a 5-year period, (71% at 3 years, 91% at 10 years). Hence, the term “usually” is strongly substantiated by the data.

The second treatment added an illustration of the different profiles of returns offered by cash savings and equities. Cash savings offer constant returns at a sure interest rate (which might vary over time). In contrast, stocks, shares and funds offer volatile returns, which may be positive or negative on any day. However, as the evidence above shows, returns on stocks, shares and funds over the medium-term are higher than those on cash savings. We illustrated this in Figure 4 using the picture shown in the left-side panel, which shows the upward but volatile pattern typically seen in the returns profiles of stocks, shares and funds.

1.2 Phase II

From the first phase, we selected the journey that was most successful in increasing the amount subjects allocated to stocks and funds, consequently decreasing the allocation to cash. This chosen journey served as the baseline (control group) for Phase II. Phase II was a second RCT featuring three additional treatment arms. In the first arm, subjects were informed of the benefits of choosing diversified products, specifically funds (see Figure 5). The second arm highlighted the advantages of a drip-feeding (pound cost averaging) strategy (see Figure 6). In the third arm, subjects were informed about the liquidity of stock and fund investments (see Figure 7). In each case, the information disclosure took the form of a statement of fact, e.g., “You can reduce your risk by spreading your investment across multiple stocks, shares and funds”, followed by an intuitive explanation, see Figure 5-7 for further details.

1.3 Survey Design and Sample

We used the Prolific platform to deploy the survey, using a Qualtrics interface. Phase I was deployed to 3,000 individuals (who self-report income of at least £20,000). For analysis, we omit individuals who did not complete the survey, and the 5% of individuals who were the quickest in reading the risk warnings, as they were likely not paying sufficient attention. The resulting sample is 2,760 individuals. In some analysis the sample size is slightly lower due to the availability of covariates in some responses. In this Phase I sample, the respondents had an average age 39, 63% are female, and 88% white. 60% had a personal income £20k - £30k, though 15% with personal income over £40k. The sample includes broad regional coverage and education coverage; see the Supplementary Tables, which also show that the randomisation worked to achieve balance, with tests confirming that the sample is balanced across treatment and controls.

Figure 1: Phase I Trial Standard Risk Warning

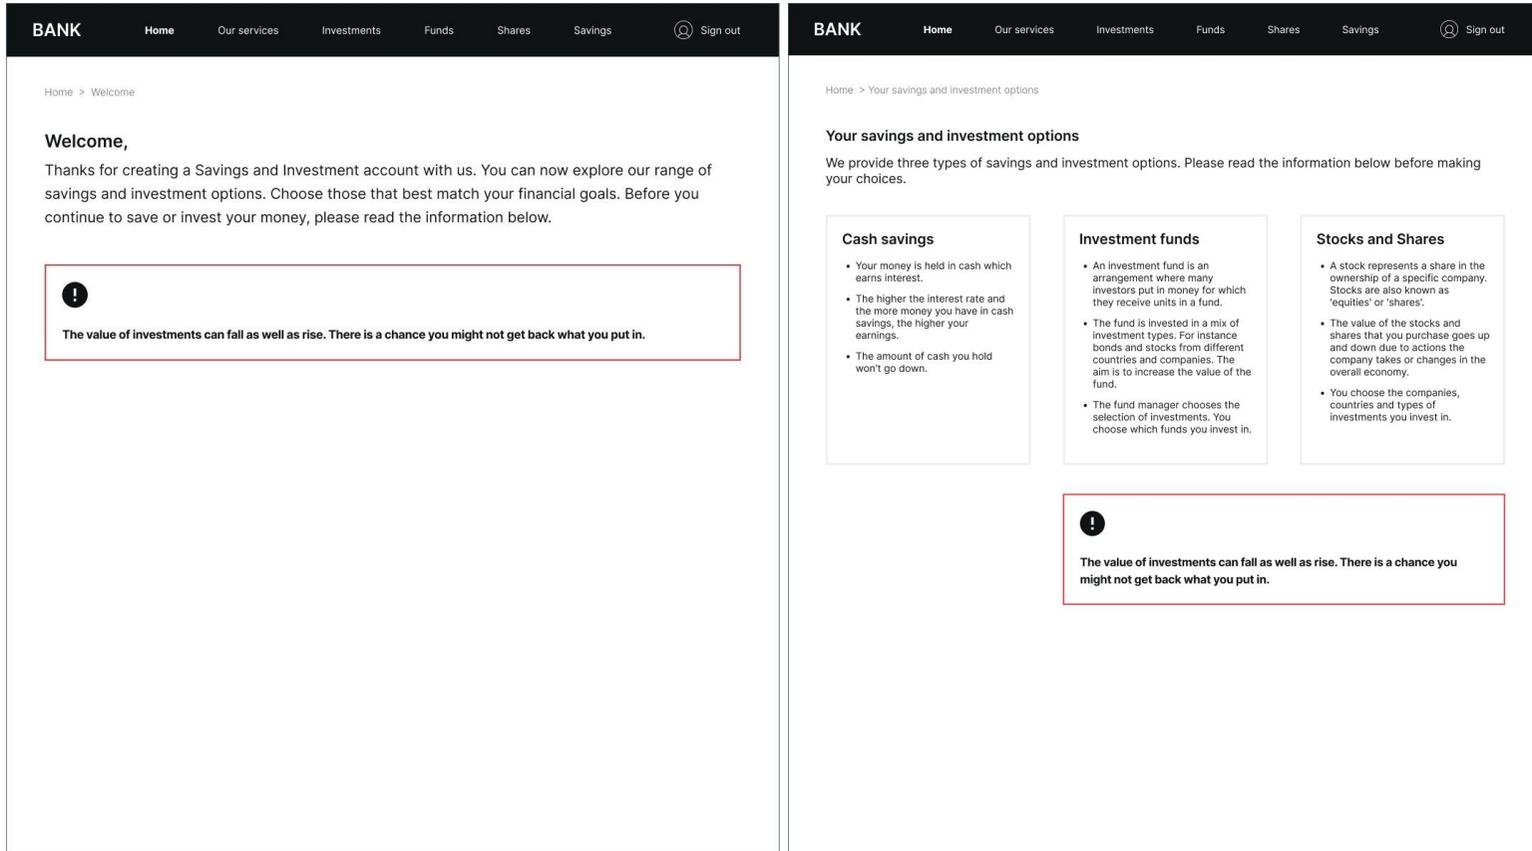

Figure 2: Investment Selection Screen

Please imagine you have received £10,000 to save and/or invest. You can choose how to distribute this across cash savings, funds, and stocks & shares. However, all the money needs to be saved and/or invested. When you make your decisions, please consider that you expect to keep the money in the account for **7 years** or longer. You have the option to save and/or invest all the money upfront or to distribute it equally over the next 12 months.

For each investment or cash saving, enter the total amount you'd like to allocate. Then, choose one of the two allocation methods:

- **All at once:** Your total amount is invested at the start of the year (e.g., if you enter £1200, this means £1200 is invested once.)
- **Spread over 12 months:** Your total amount is split into 12 equal monthly investments (e.g., if you input £1200, this means £100 will be invested every month.)

You have the following investment opportunities at your disposal:

	How would you allocate the £10,000 across these options?		Investment Frequency	Allocation Amount £
	Allocate funds	Do not allocate funds		
Global Fund An investment in a variety of businesses all around the world.	<input type="radio"/>	<input type="radio"/>	<input type="text" value="v"/>	<input type="text"/>
Tech Sector Fund An investment concentrated on tech businesses worldwide.	<input type="radio"/>	<input type="radio"/>	<input type="text" value="v"/>	<input type="text"/>
Pharma Company Stock An investment in a single pharmaceutical company.	<input type="radio"/>	<input type="radio"/>	<input type="text" value="v"/>	<input type="text"/>
Tech Company Stock An investment in a single tech company.	<input type="radio"/>	<input type="radio"/>	<input type="text" value="v"/>	<input type="text"/>
Cash Saver Account A cash savings account with an interest rate.	<input type="radio"/>	<input type="radio"/>	<input type="text" value="v"/>	<input type="text"/>
Total: 0				You have left £10000.

Home > Your savings and investment options

Your savings and investment options

We provide three types of savings and investment options. Please read the information below before making your choices.

Cash savings

- Your money is held in cash which earns interest.
- The higher the interest rate and the more money you have in cash savings, the higher your earnings.
- The amount of cash you hold won't go down.

Investment funds

- An investment fund is an arrangement where many investors put in money for which they receive units in a fund.
- The fund is invested in a mix of investment types. For instance bonds and stocks from different countries and companies. The aim is to increase the value of the fund.
- The fund manager chooses the selection of investments. You choose which funds you invest in.

Stocks and Shares

- A stock represents a share in the ownership of a specific company. Stocks are also known as 'equities' or 'shares'.
- The value of the stocks and shares that you purchase goes up and down due to actions the company takes or changes in the overall economy.
- You choose the companies, countries and types of investments you invest in.

!

The value of investments can fall as well as rise. There is a chance you might not get back what you put in. But over longer periods of time (e.g. 5 years or more), riskier investments such as stocks, shares and funds usually give you higher returns compared to cash savings.

!

The value of investments can fall as well as rise. There is a chance you might not get back what you put in. But over longer periods of time (e.g. 5 years or more), riskier investments such as stocks, shares and funds usually give you higher returns compared to cash savings.

You can reduce your risk by spreading your investment across multiple stocks, shares or funds.

This means that if the price of one stock or share goes down, it will have less overall effect on the value of your investment or fund. This means you avoid putting all your eggs in one basket!

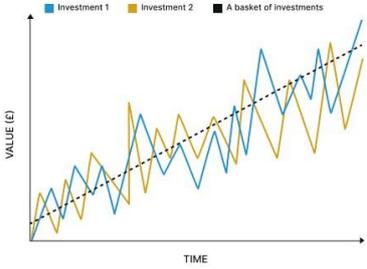

Figure 6: Phase II Trial Drip Feed Messaging

The value of investments can fall as well as rise. There is a chance you might not get back what you put in. But over longer periods of time (e.g. 5 years or more), riskier investments such as stocks, shares and funds usually give you higher returns compared to cash savings.

By investing regularly you can reduce the risk of varying prices.

You invest gradually over time. You hold any uninvested money in cash until it is invested. As the value of your investments goes up and down, the price you pay will vary. Over time, the amount you pay for the investments will average out. This helps reduce the risk that you pay one price for a single, large sum investment one day, but the value drops the next day.

You can access your money at any time when you save or invest.

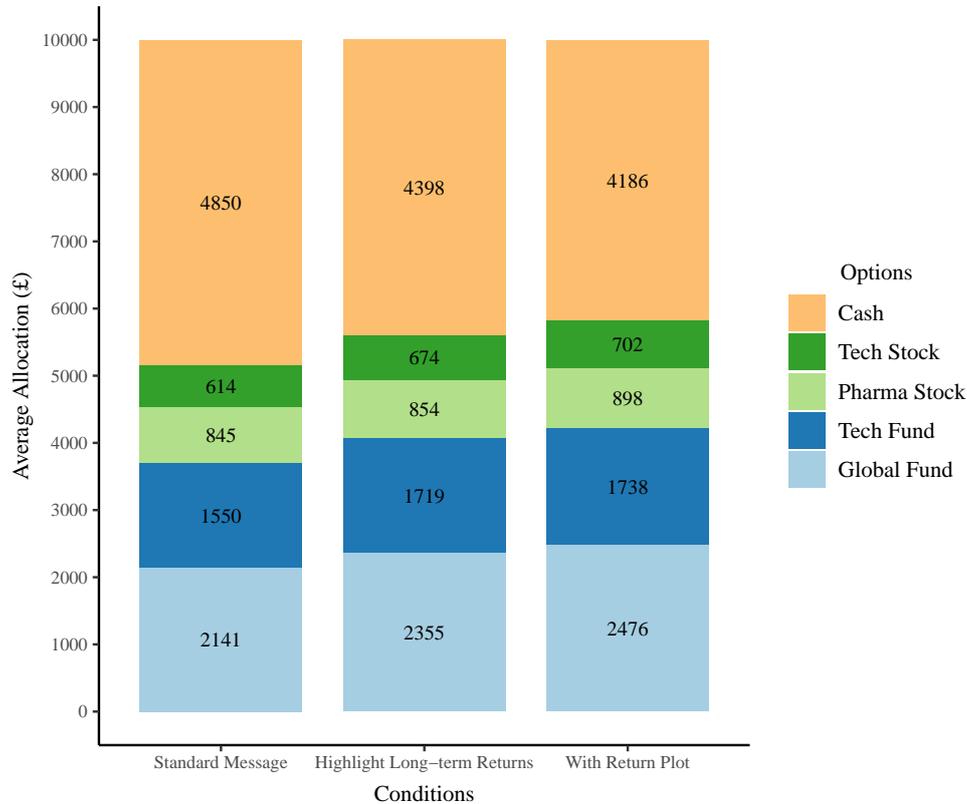

2 Phase I Results

2.1 Main Results

Results from the Phase I RCT show that both treatments increase allocation to stocks and funds. In the control journey (standard message), the average allocation is approximately £5,100 across stocks and funds and £4,900 to cash (values here are rounded to the nearest £100). This allocation in the control journey is not necessarily reflective of real-world allocations as we would not expect consumers to be approximately equally allocated across cash and risky assets in the real-world. However, the effects we measure in the RCT are the difference from this allocation in the treatment arms, hence the absolute level of allocation in the control journey is not determinant of the results of the RCT.

Treatment I (long-run returns message) increases investments in both stocks and funds, in total to £5,600, therefore decreasing cash to £4,400. Treatment II (plot) further increases stocks and funds to £5,800, therefore decreasing cash to £4,200. These effects are illustrated in Figure 8. Regression analysis presented in Table 1 confirms these relationships, with further regression estimates adding controls for demographic and other characteristics shown in the Supplementary Tables.

Figure 8: Phase I Allocations

2.2 Sub-group Analysis

On average, across the entire sample, the messaging about long-run returns leads to an increase in stocks and shares allocation by approximately £500. In further analysis, we explored whether the treatment had a more pronounced effect on specific groups. In sub-group analysis we conduct estimates for samples defined by gender (male/female), age (median-split, at age 37), saving, (median-split), region of residence, income (median-split, at £20,000 to £29,000), education (split at undergraduate degree), financial confidence (median-split), risk attitude (median-split), future orientation (median-split), loss aversion (median-split).

We find that the effect of the treatment is notably stronger for females. For women, the effect is £510 vs £390 for men (rounded to the nearest £10). This is a large, and statistically significant difference (see Supplementary Tables).

We also find:

- For older individuals effect is £670 vs £280 for younger;

- For above-median income effect is £560 vs £380 for below;
- For above-median education effect is £610 vs £130 for below;
- For low-confidence individuals effect is £700 vs £220 for high-confidence.

Table 1: Phase I Allocations (OLS Regression)

	<i>Dependent variable:</i>	
	Cash (amount)	Cash (dummy)
	(1)	(2)
Highlight Long-term Returns	−456.53*** (139.80)	−0.03* (0.02)
With Return Plot	−661.81*** (140.30)	−0.06*** (0.02)
Constant	4,854.96*** (98.99)	0.90*** (0.01)
Observations	2,754	2,754
R ²	0.01	0.01
Adjusted R ²	0.01	0.005

Notes: *p<0.1; **p<0.05; ***p<0.01

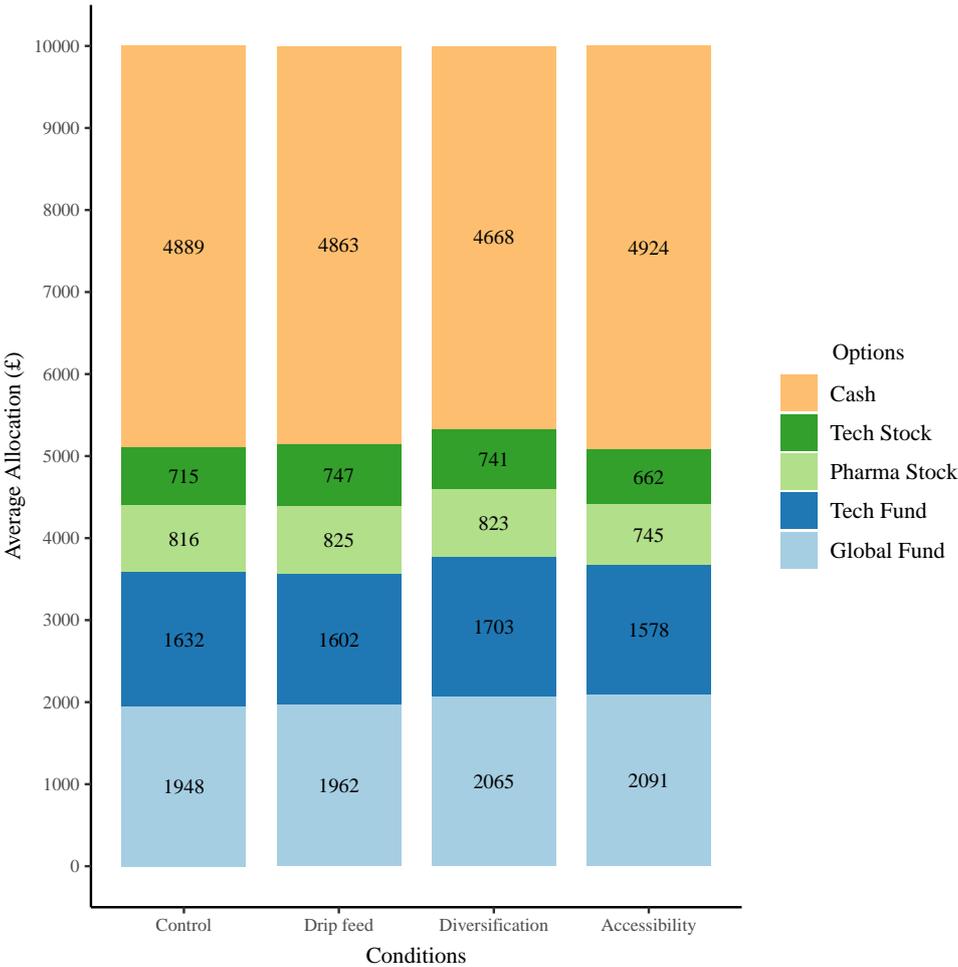

In further analysis, we explored the existence of regional variation in the impact of these treatments. Results indicate no clear pattern in regional variation. There is evidence of slightly stronger effects of the long-run returns treatment on lowering cash (raising stock and fund investments) among individuals in Southern England and also Northern England, with no clear pattern across other regions (Midlands, Northern Ireland, Scotland and Wales).

Taken together, our results show that long-term returns messaging is particularly effective in moving preferences of older, higher income / education and less financially confident females.

3 Phase II Results

Phase II was implemented using the most effective risk warning from Phase I. This decision was based on evaluating the effects of the treatments in Phase I alongside their impact on the customer journey screens. The long-term returns treatment had the largest marginal effect on reducing cash allocation among participants. While the returns plot treatment did result in a further, albeit smaller, reduction in cash allocation, it necessitated the inclusion of an additional visual element on the screen for Phase II. Considering the balance between effectiveness and simplicity, and to avoid potential information overload for participants, we decided to proceed with the long-term returns treatment without the plot as the baseline for Phase II. This approach was deemed to offer the optimal combination of impact and user-friendly interface.

Figure 9: Phase II Allocations

Phase II was also implemented using Prolific, utilizing Qualtrics for survey creation and

distribution. The survey was deployed to 4,155 individuals, retaining 3,639 after cleaning. Due to a limited sample available on the platform, the minimum income threshold of £20,000 was removed. In the Phase II sample, 73% of respondents have income under £20,000. This means that the Phase II sample has a lower average income compared with the Phase I sample, though in the Phase I sample 60% of individuals have an income in the range £20,000 - £29,000. The samples are comparable in terms of average age (38.8 vs 37.7), the proportion female (65% vs 70%) and the proportion with an undergraduate degree (44% vs 39%).¹ The Phase I and Phase II samples are also similar in the average level of investment in stocks and shares, in the range £5,000 to £5,500 in both samples. This allays concerns that the Phase II results might apply to a very different sample to that included in Phase I.

3.1 Diversification Treatment

Results from Phase II indicate the effectiveness of both the diversification and drip feed treatments, as depicted in Figure 9. The diversification treatment led to an additional increase in stocks and funds holdings of £220, with £190 of this amount flowing into mutual funds. Regression analysis in Table 2 shows that there is more uncertainty around these results than for the impact of the long-term returns messaging in Phase I. The coefficients on the diversification treatment dummy in Table 2 are less well-defined, but indicate positive effects on mutual fund holdings albeit with a higher degree of uncertainty.

¹ Further demographic information for this sample is available in the Summary Tables.

Table 2: Phase II Allocations (OLS Regression)

	<i>Dependent variable:</i>		
	Cash (1)	Mutual fund (2)	Spread over 12 months (3)
Drip feed	-25.47 (147.72)	-16.18 (129.24)	825.86*** (134.94)
Diversification	-220.64 (149.06)	187.46 (130.40)	341.40** (136.16)
Accessibility	35.59 (149.01)	88.87 (130.37)	-37.63 (136.12)
Constant	4,888.73*** (105.22)	3,580.41*** (92.05)	1,785.94*** (96.12)
Observations	3,632	3,632	3,632
R ²	0.001	0.001	0.01
Adjusted R ²	0.0002	0.0000	0.01

Notes: *p<0.1; **p<0.05; ***p<0.01

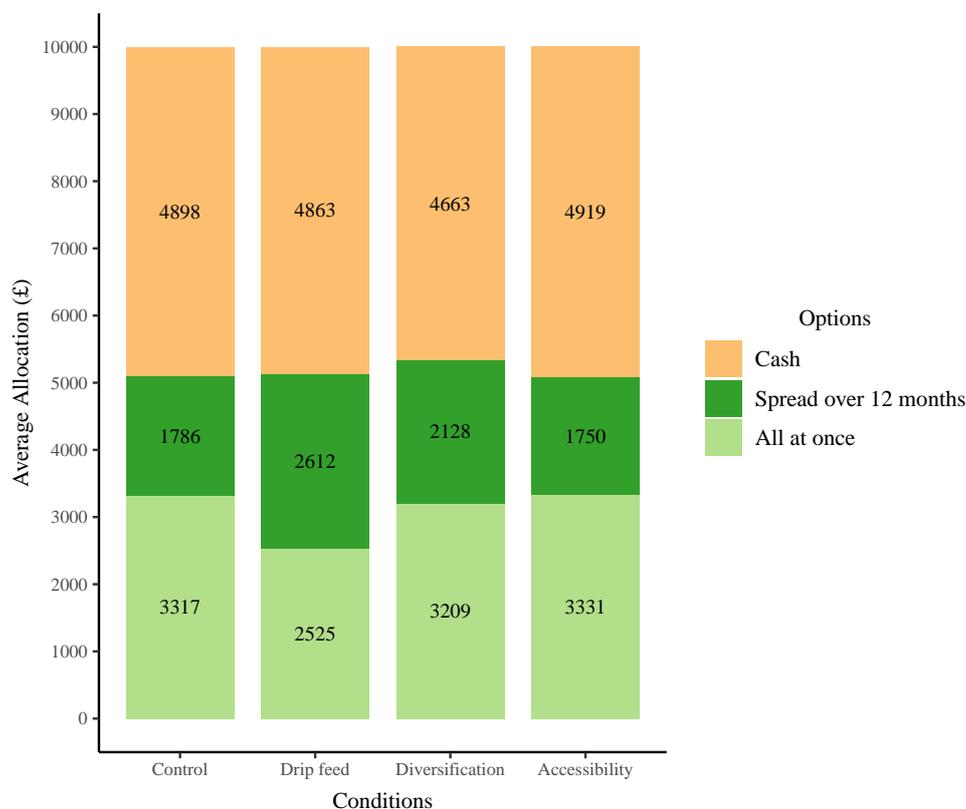

3.2 Drip-Feed Treatment

The drip feed treatment increases likelihood of spreading investment over 12 months by 14.2%, on average allocating £830 of their investment to be spread, illustrated in Figure 10. Regression analysis presented in Table 2 confirms these relationships, with further regression estimates adding controls for demographic and other characteristics shown in the Supplementary Tables.

3.3 Liquidity Treatment

The liquidity message had no effect on cash holding, investment choice (mutual fund vs stocks), or spreading investments. As can be seen in the final column of Figure 9, the allocations across categories resemble those in the control condition which does not have the additional liquidity message. This is also reflected in the regression estimates in Table, where the coefficient values on the accessibility treatment dummy in each column are low, and the standard errors high, indicating no clear effect of this treatment on any of the outcomes of interest. This result may have arisen due to the priming of a 7-year investment period, which minimises the importance

Figure 10: Phase II Drip-feed Allocations

of liquidity considerations.

3.4 Sub-group Analysis

As in Phase I, some interventions are more effective among subgroups. Specifically, we find that the diversification treatment results in larger reductions in cash among females, younger, below median education and above-median saving. These same groups show the largest increases in investment in mutual funds. The drip feed treatment is most effective among older, below median income; with low confidence, low risk aversion and low loss aversion. This is consistent with drip feeding being effective among those who are not particularly averse to risk and loss i.e. those who are more likely to invest in risky assets. The drip-feed treatment therefore appears to work to change the investing patterns of those with a tendency to invest in stocks, shares and funds.

4 Discussion

The experimental results highlight that information disclosures are a promising avenue for influencing consumer investment choices. The information disclosures may help to counter mis-conceptions of the riskiness of stock and fund investments, and also prompt consumers to diversify their investments and spread their investment amounts over time. Improved understanding among consumers, as a result of these disclosures, is likely to lead to more informed and beneficial consumer choices.

4.1 Further Research

Further research in this area appears highly promising, particularly in testing these information disclosures within real-world consumer choice environments. Further research could address some of the limitations of the current study.

While the experimental design presented in this report is similar to a standard consumer journey, it can only do so in a hypothetical setting in which consumers are not financially vested in their decisions. In a real-world setting, there is potential for the responses of consumers to be stronger as they have a greater incentive to pay attention to the disclosures as presented in the journey, though in the real world setting it may be more difficult to overcome consumer mis-conceptions compared to in the hypothetical choice environment.

In addition, one element of the consumer decision process not taken into account in the current research design is the role of advisers. A substantial portion of the investment market, for example, is accounted for by advised sales. The treatment effects we observe in the research design here may vary in a setting in which the adviser also has input into the consumer decision.

Further research in a real-world journey would therefore be highly valuable for learning more about the efficacy of these information disclosures and their potential to be deployed in consumer choice journeys.

A.8 Phase II Regression Analysis

Table A31: Phase II Allocations OLS Regressions (with Demographics)

	<i>Dependent variable:</i>		
	Cash (1)	Mutual fund (2)	Spread over 12 months (3)
Drip feed	-85.74 (145.61)	20.42 (128.25)	928.86*** (132.95)
Diversification	-267.90* (146.45)	225.13* (128.99)	391.41*** (133.72)
Accessibility	24.47 (146.60)	84.36 (129.12)	-8.26 (133.85)
Constant	8,189.21*** (955.27)	1,337.40 (841.39)	3,326.30*** (872.22)
Demographics	Yes	Yes	Yes
Observations	3,622	3,622	3,622
R ²	0.06	0.04	0.07
Adjusted R ²	0.05	0.03	0.06

Notes: Female = 0 if male, = 1 if female. Ethnicity includes White, Asian, Mixed, Black, and Other. White is the reference in regression. Personal Income ranges from '£20,000 - £29,999' to 'More than £150,000'. '£20,000 - £29,999' is the reference in regression. Education ranges from 'No formal qualifications' to 'Doctorate degree (PhD/other)'. 'No formal qualifications' is the reference in regression. Age² is Age squared.
